Architecture vs Design

Quality	Metrics	Approach
• Performance	• Response time	• Caching
• Scalability	• Throughput	• NIO
• Availability	• tps	• Compression
• Maintainability	• Latency	• JIT (Lazy loading)
• Security (Trust)	• Resource usage	• Extensibility
• Reliability (Trust)		• Testability
• Robustness		• KISS
• Portability		• Doc
• Interoperability		• Observability
• Cost, TTM		• ACID
		•

Constraints view

Must support popular Desktop OS and Mobile OS

Should work on a low bandwidth network

Use Opensource only

Use Postgres database version xyz

Use GCP cloud

Yearly Cloud Billing should not exceed 1 million dollars - cost

Should be in production on April 1st 2023 - (next financial year)

Data should be kept for 8 years

Self Driving Car Rental

Should work on Azure Cloud

GDPR Compliance

Seed Quality Scenarios

Quality	Source (who)	Stimulus (action)	Artifact (which)	Environment (context)	Response (output)	Measure (scale)
Performance	As a user	I want to upload a 2 MB file	From Mobile Client	During Peak Load	The File is uploaded	In < 3 secs
Maintainability	Developer	Want to replace the storage	In the cloud API	During maintenance	The storage is replaced	In < 20 man days
Security	unknown identity	requests to download a file	In the portal	During Normal load.	block access to the data and record the access attempts	100% probability of detecting the attack, 100% probability of denying access
Availability	The Database	Failed	In the Data Centre	During Operational Hours	Secondary is made Primary	In < 2 minutes

Quality	Source (who)	Stimulus (action)	Artifact (which)	Environment (context)	Response (output)	Measure (scale)
Availability	Processor	Stops working	Central System	Peak hours	Notify Provide degraded mode	< 5 min degraded mode
Reliability	Consumer WebSite	Send purchase order request	To Xyz App	Duplicate Request	the consumer is not double-charged and one POS is placed.	99% of the time
Maintainability	New Display System	Is Installed	Int the Bus Stop	Off Peak hours	The Display system starts showing bus arrival information	within 30 minutes

Assumptions View

Will use open source Technologies only

For offline scenarios in native app or any of services going down in backend last available timeline will be visible.

System will be eventually consistent.

Eclipse IDE. Downloading the basic Eclipse product provides you little more than a fancy editor. However, once you start adding plug-ins, it becomes a highly customizable and useful product.

An application is required to perform a **variety of tasks** of **varying complexity** on the information that it processes. The processing tasks performed by each module, or the deployment requirements for each task, **could change** as business requirements are updated. Also, **additional processing** might be required in the future, **or the order** in which the tasks performed by the processing could change. A solution is required that addresses these issues, and increases the possibilities for code reuse.

A workflow implementation. The implementation of a workflow contains concepts like the order of the different steps, evaluating the results of steps, deciding what the next step is, etc.

A task scheduler. A scheduler contains all the logic for scheduling and triggering tasks

Internet browses plug-ins add additional capabilities that are not otherwise found in the basic browser

Networking engineering is a complicated task, which involves software, firmware, chip level engineering, hardware, and electric pulses. To ease network engineering, the whole networking concept is decomposed into more manageable parts.

If you need query language support, Cassandra is the better fit for you.

Use Cases

Content Management System

Fraud Detection

- We extract entities from a large database of business activities, make relationships between them.

- We can then use a technique called “Entity Link Analysis” to identify suspicious links between types of entities that may indicate fraudulent behaviour.

- We will use entities from people such as names and dates of birth, as well as contextual entities such as IP addresses, device identifiers and access times.

- We can then analyse the links between these entities and mark up those that have previously been marked as fraudulent. When entities that are marked as fraudulent start to intersect those that are not marked as fraudulent, suspicions begin to arise. For example, use of multiple bank accounts on a single device that has been previously used to access fraudulent accounts.

Product Catalogue

- 3 different systems to maintain: RDBMS, Search engine, Caching layer
- RDBMS schema is complex and static
- Applications needs to talk many languages

- With the API layer, the application just issues a single call, thus reducing complexity and latency
- No need for a caching layer since MongoDB's read performance is close to Memcache and the likes
- The schema is dynamic and maps well to the API calls

An inventory system that might want full ACID. I was very unhappy when I bought a product and they said later they were out of stock. I did not want a compensated transaction. I wanted my item!

Asset Management

Network Mapping

- when mapping relationships between connected physical/virtual hardware and the services that they support. An enterprise will use CMDBs (configuration management databases) and/or service catalogs to keep inventory of their systems. They are used to keep track of components, their purpose, software versions and the interdependencies between them.
- relationships between infrastructure components not only enables interactive visualisations of the network estate but also network tracing algorithms to walk the graph. For example, algorithms for:

Dependency Management: Identify single points of failure and simulate the impact of their failure on services, to identify cascading failures before they happen.

Bottleneck Identification: Find weak links in network routing that could cause bottlenecks at times of high network utilisation.

Latency Evaluation: Estimate latency across paths in the network, and the impact on services accessed from various geographic regions.

- Real-time recommendations and advertising **can quickly access and present** new recommendations or ads as a web visitor moves throughout a site.

- build social relationship to enhance content personalization

- Store user session details and preference. All the information lend themselves to fast reads and writes.

transactions logging in Banking and Finance, events logging in web analytics or messaging systems, time-series data, tracking of inventory, IoT (Internet of Things) data, weather tracking,

column-family	Columnar
sparse data model	
multi-dimensional map	
column-families are not independently accessible.	every column is stored separately
NoSQL	SQL interface
Reads that use the partition key are incredibly fast	optimized for read-mostly analytical workloads
high throughput writes	very slow writes
	data warehouses

	MongoDB	Cassandra
Expressive object model	Yes	No
Secondary indexes	Yes	No
No downtime on node failure	No	Yes
High write throughput	No	Yes

- Cassandra is optimized for really high throughput on writes. **If your use case is read-heavy (like cache) then Cassandra might not be an ideal choice.**
- It does not support complete transaction management across the tables. Not ACID compliant system.
- Secondary Index not supported. Have to rely on Elastic search /Solr for Secondary index and the custom sync component has to be written.

not possible to aggregate data in a query. Sums and averages like information have to be done by the client-side application.

Use Cassandra as the primary data store for capturing information as it arrives into the system; but then build “query-optimised views” of subsets of that data in other databases specialised to the kinds of access users require. Use an indexing engine such as SOLR to provide full-text search across records, or a graph database such as Neo4j to store metadata in a way that supports “traversal-heavy” queries that join together many different kinds of entity. Use an RDBMS when you need the full power and flexibility of SQL to express ad hoc queries that explore the data in multiple dimensions.

Wide Column

- Spotify uses Cassandra to store user profile attributes and metadata about artists, songs, etc. for better personalization
- Facebook initially built its revamped Messages on top of HBase, but is now also used for other Facebook services like the Nearby Friends feature and search indexing
- Outbrain uses Cassandra to serve over 190 billion personalized content recommendations each month

A fact table has two types of columns: those that include fact (purely numerical facts) and those that are foreign keys to the dimension table.

Dimension tables store the descriptive attributes of entities across the business enterprise and function as common lookup tables

Star schema

A star schema has a single fact table in the center, containing business "facts" (like transaction amounts and quantities). The fact table connects to multiple other dimension tables along "dimensions" like time, or product. Star schemas enable users to slice and dice the data

Skan.

© SKAN.AI 2019 CONFIDE

there are two basic models which are used in dimensional modeling

- Star Model
- Snowflake Model

COMMON COMPARISONS BETWEEN

MYSQL & NOSQL

	MySQL	NoSQL
Nature	Relational Database	Non-Relational Database
Design	Based on the concept of tables	Based on the concept of documents
Scalable	Tough to scale due to its relational nature	Easily scalable big data compared to relational
Model	Detailed database model is needed before creation	No need of a detailed database model
Community	Vast community available	Community is growing rapidly, but still smaller compared to MySQL
Standardization	SQL is standard language	Lacks standard query language
Schema	The Schema is rigid	The Schema is dynamic
Flexibility	Not very flexible in terms of design	Very flexible in terms of design
Insertions	Inserting new columns or fields affect the design	No effect on the design with the insertion of new columns or fields

Facebook, Wikipedia, Quora, Flickr	MySQL
Twitter	MySQL for tweets and users their own special kind of graph database, FlockDB, built on top of MySQL their own version of Memcached
LinkedIn	Oracle Database and Voldemort
YouTube	MySQL -> BigTable
Microsoft, Myspace	***SQL Server***
Yahoo	***PostgreSQL***

Key Value	○ Twitter uses Redis to deliver your Twitter timeline
	○ Pinterest uses Redis to store lists of users, followers, unfollowers, boards, and more
	○ Coinbase uses Redis to enforce rate limits and guarantee correctness of Bitcoin transactions
	○ Quora uses Memcached to cache results from slower, persistent databases
Graph	○ Walmart uses Neo4j to provide customers personalized, relevant product recommendations and promotions
	○ Medium uses Neo4j to build their social graph to enhance content personalization
	○ Cisco uses Neo4j to mine customer support cases to anticipate bugs
Document	○ SEGA uses MongoDB for handling 11 million in-game accounts
	○ Cisco moved its VSRM (video session and research manager) platform to Couchbase to achieve greater scalability
	○ Aer Lingus uses MongoDB with Studio 3T to handle ticketing and internal apps
	○ Built on MongoDB, The Weather Channel's iOS and Android apps deliver weather alerts to 40 million users in real-time

Generation 1: The beginning of Big Data at Uber (Before 2014)

Data was scattered across different OLTP databases.

Generation 1 (2014-2015) - The beginning of Big Data at Uber

Aggregating all of Uber's data in one place. Developed multiple ad hoc ETL jobs that copied data from different sources (i.e. AWS S3, OLTP databases, service logs, etc.) into Vertica.

Data was ingested with no transformation during ingestion.

Generation 2 (2015-2016) - The arrival of Hadoop

only over 100 gb of new data was added every day. Since HDFS and Parquet do not support data updates, each run of the ingestion job had to convert the entire, over 100 tb dataset for that specific table.

Generation 3 (2017-present) - Let's rebuild for long term

Incremental ingestion:

	Kinesis Data Streams	Kinesis Firehose
Purpose	Low latency streaming service for ingest at scale	Data transfer service to load streaming data into Amazon S3, Redshift, Elasticsearch & Splunk
Provisioning	Managed service but needs configuration for shards.	Fully managed service, no administration.
Processing	Real Time (~200ms latency for classic, ~70ms for enhanced fan out)	Near real time (depends on buffer size OR buffer time min. 60 secs)
Scaling	Must manage scaling (configure shards)	Automated Scaling – as per the demand
Data Storage	Configurable from 1 to 7 days	Does not provide data storage
Replay capability	Supports replay capability	Does not support replay capability
Producers	Need to write code for producer. Supports SDK, Kinesis Agent, KPL, CloudWatch, IoT	Need to write code for producer. Supports KPL, Kinesis Agent, Data Streams, CloudWatch, IoT
Consumers	Open ended. Supports multiple consumers and destinations. Supports KCL and Spark.	Closed ended. Handled by Firehose. Does not support KCL or Spark.

Data
1-5 msec
5 mim/ 5 hours
Amazon S3
Amazon S3 Glacier
$0.025 per GB per month
$0.004 per GB per month + extraction cost

	S3	**S3 Glacier**
Access speed	Hi	Low
API availability	Yes	Yes
Data storage cost	Relatively high	Very low
Object size	Up to 5 Tb	40 Tb
Accommodation in regions	Many regions	Average
Static Web Content	Yes	No
Supporting Versioning	Yes	No

	Data Streams	Data Firehose	Data Analytics	Video Streams
Short definition	Scalable and durable real-time data streaming service.	Capture, transform, and deliver streaming data into data lakes, data stores, and analytics services.	Transform and analyze streaming data in real time with Apache Flink.	Stream video from connected devices to AWS for analytics, machine learning, playback, and other processing.
Data sources	Any data source (servers, mobile devices, IoT devices, etc) that can call the Kinesis API to send data.	Any data source (servers, mobile devices, IoT devices, etc) that can call the Kinesis API to send data.	Amazon MSK, Amazon Kinesis Data Streams, servers, mobile devices, IoT devices, etc.	Any streaming device that supports Kinesis Video Streams SDK.
Data consumers	Kinesis Data Analytics, Amazon EMR, Amazon EC2, AWS Lambda	Amazon S3, Amazon Redshift, Amazon Elasticsearch Service, generic HTTP endpoints, Datadog, New Relic, MongoDB, and Splunk	Analysis results can be sent to another Kinesis stream, a Kinesis Data Firehose delivery stream, or a Lambda function	Amazon Rekognition, Amazon SageMaker, MxNet, TensorFlow, HLS-based media playback, custom media processing application
Use cases	– Log and event data collection – Real-time analytics – Mobile data capture – Gaming data feed	– IoT Analytics – Clickstream Analytics – Log Analytics – Security monitoring	– Streaming ETL – Real-time analytics – Stateful event processing	– Smart technologies – Video-related AI/ML – Video processing

S. No.	Amazon DynamoDB	Amazon Redshift
1	It was developed by Amazon in 2012.	It was developed by Amazon in 2012.
2	It is hosted, scalable database service by Amazon with data stored in Amazon cloud.	It is large scale data warehouse service for use with business intelligence tools.
3	It does not support SQL query language.	It supports SQL query language. But it does not fully support an SQL-standard.
4	It does not provide concept of Referential Integrity. Hence, no Foreign Keys.	It provides concept of Referential Integrity. Hence, there are Foreign Keys.
5	Its Primary database models are Document store and Key-value store.	Its primary database model is Relational DBMS.
6	It does not support Server-side scripting.	It supports user-defined functions for Server-side scripting in python.
7	Eventual Consistency and Immediate Consistency are used to ensure consistency in distributed system.	Immediate Consistency is used to ensure consistency in distributed system.
8	It does not offers API for user-defined Map/Reduce methods. But maybe implemented via Amazon Elastic MapReduce.	It does not offer API for user-defined Map/Reduce methods.
9	It supports secondary indexes.	It supports restricted secondary indexes.

Data Sources
S3
EMR
S3
Redshift
QuickSight
Upload data from multiple sources into S3
Use Amazon EMR to transform and cleanse the data (ETL)
Load formatted and cleansed data into S3
Redshift loads data in parallel optimizing it for fast analytics queries
Analyze and visualize data with Amazon Quicksight
Ad-hoc access to data using Athena
Athena can query aggregated datasets as well

              p.Year >= yearStart &&
              p.Year <= yearEnd
        orderby p.Year ascending
        select p;
```

```
"abcdef".AsParallel().Select (c => char.ToUpper(c)).ToArray()
```

Partitioning Algorithms in PLINQ

- Several partitioning schemes built-in
  - Chunk
    - Works with any IEnumerable<T>
    - Single enumerator shared; chunks handed out on-demand

  - Range
    - Works only with IList<T>
    - Input divided into contiguous regions, one per partition

  - Stripe
    - Works only with IList<T>
    - Elements handed out round-robin to each partition

  - Hash
    - Works with any IEnumerable<T>
    - Elements assigned to partition based on hash code

- Custom partitioning available through Partitioner<T>
  - Partitioner.Create available for tighter control over built-in partitioning schemes

Reactive Programming != Reactive System

The Reactive Manifesto

The Reactive Manifesto (http://www.reactivemanifesto.org/) is a document defining the four reactive principles

Responsive
Scalable
Resilient
Event-Driven

reactive manifesto

Using **reactive programming does not build a reactive system**. Reactive systems, as defined in the reactive manifesto, are an architectural style to *build responsive distributed systems*. Reactive Systems could be seen as distributed systems done right. A reactive system is characterized by four properties:

- **Responsive**: a reactive system needs to handle requests in a reasonable time (I let you define reasonable).
- **Resilient**: a reactive system must stay responsive in the face of failures (crash, timeout, 500 errors…), so it must be designed for failures and deal with them appropriately.
- **Elastic**: a reactive system must stay responsive under various loads. Consequently, it must scale up and down, and be able to handle the load with minimal resources.
- **Message driven**: components from a reactive system interacts using asynchronous message passing.

Despite the simplicity of these fundamental principles of reactive systems, building one of them is tricky. Typically, each node needs to embrace an asynchronous non-blocking development model, a task-based concurrency model and uses non-blocking I/O.

Cricket score,
Stock exchange,
Bidding,
time,

Multiple values (*)

Single value (1)

Array

```
res =
  stocks
  .filter(q => q.symbol == 'FB')
  .map(q => q.quote)

res.forEach(x =>
  ...
```

Observable

```
res =
  stocks
  .filter(q => q.symbol == 'FB')
  .map(q => q.quote)

res.forEach(x =>
  ...
```

Object

```
var y = f(x);
var z = g(y);
```

Promise

```
fAsync(x).then(...);
gAsync(y).then(...);
```

Threat Modeling

Threat Modeling Method	Features
STRIDE	• Helps identify relevant mitigating techniques • Is the most mature • Is easy to use but is time consuming
PASTA	• Helps identify relevant mitigating techniques • Directly contributes to risk management • Encourages collaboration among stakeholders • Contains built-in prioritization of threat mitigation • Is laborious but has rich documentation
LINDDUN	• Helps identify relevant mitigation techniques • Contains built-in prioritization of threat mitigation • Can be labor intensive and time consuming
CVSS	• Contains built-in prioritization of threat mitigation • Has consistent results when repeated • Has automated components • Has score calculations that are not transparent
Attack Trees	• Helps identify relevant mitigation techniques • Has consistent results when repeated • Is easy to use if you already have a thorough understanding of the system
Persona non Grata	• Helps identify relevant mitigation techniques • Directly contributes to risk management • Has consistent results when repeated • Tends to detect only some subsets of threats
Security Cards	• Encourages collaboration among stakeholders • Targets out-of-the-ordinary threats • Leads to many false positives
hTMM	• Contains built-in prioritization of threat mitigation • Encourages collaboration among stakeholders • Has consistent results when repeated
Quantitative TMM	• Contains built-in prioritization of threat mitigation • Has automated components • Has consistent results when repeated
Trike	• Helps identify relevant mitigation techniques • Directly contributes to risk management • Contains built-in prioritization of threat mitigation • Encourages collaboration among stakeholders • Has automated components • Has vague, insufficient documentation
VAST Modeling	• Helps identify relevant mitigation techniques • Directly contributes to risk management • Contains built-in prioritization of threat mitigation • Encourages collaboration among stakeholders • Has consistent results when repeated • Has automated components • Is explicitly designed to be scalable • Has little publicly available documentation
OCTAVE	• Helps identify relevant mitigation techniques • Directly contributes to risk management • Contains built-in prioritization of threat mitigation • Encourages collaboration among stakeholders • Has consistent results when repeated • Is explicitly designed to be scalable • Is time consuming and has vague documentation

PASTA

STAGE I - Definition of the Objectives (DO)	• DO 1.1 - Document the business requirements • DO 1.2 – Define the security/compliance requirements • DO 1.3 – Define the business impact • DO 1.4 – Determine the risk profile
Stage II - Definition of the Technical Scope (DTS)	• DTS 2.1 – Enumerate Software components • DTS 2.2 – Identify Actors & Data Sinks/Source • DTS 2.3 – Enumerate System-Level services • DTS 2.4 – Enumerate 3rd Party infrastructure. • DTS 2.5 – Assert completeness of secure design.
Stage III - Application Decomposition and Analysis (ADA)	• ADA 3.1 – Enumerate all application use cases • ADA 3.2 – Document Data Flow Diagrams (DFDs) • ADA 3.3 – Security functional analysis & the use of trust boundaries
Stage IV - Threat Analysis (TA)	• TA 4.1 – Analyze the overall threat scenario • TA 4.2 – Gather threat information from internal threat sources • TA 4.3 – Gather threat information from External threat sources • TA 4.4 – Update the threat libraries • TA 4.5 – Threat agents to assets mapping. • TA 4.6 – Assignment of the probabilistic values for identified threats
Stage V - Weakness and Vulnerability Analysis (WVA)	• WVA 5.1 – Review/correlate existing vulnerabilities • WVA 5.2 – Identify weak design patterns in the architecture • WVA 5.3 – Map threats to vulnerabilities • WVA 5.4 – Provide Context risk Analysis based upon Threat-Vulnerability • WVA 5.5 – Conduct targeted vulnerability testing
Stage VI - Attack Modeling & Simulation (AMS)	• AMS 6.1 – Analyze the attack scenarios • AMS 6.2 – Update the attack library/vectors and the control framework • AMS 6.3 – Identify the attack surface and enumerate the attack vectors • AMS 6.4 – Assess the probability and impact of each attack scenario. • AMS 6.5 – Derive a set of cases to test existing countermeasures. • AMS 6.6 – Conduct attack driven security tests and simulations
STAGE VII - Risk Analysis & Management (RAM)	• RAM 7.1 – Calculate the risk of each threat • RAM 7.2 – Identify countermeasures and risk mitigations measures • RAM 7.3 – Calculate the residual risks • RAM 7.4 – Recommend strategies to manage risks

Steps 1 to 3
Steps 4 to 6
Steps 7 to 8
Step 9

Utility
Performance
Data Latency
(M,L) Minimize storage latency on customer DB to 200 ms.
(H,M) Deliver video in real time
Transaction Throughput
Modifiability
New product categories
Change COTS
(L,H) Add CORBA middleware in < 20 person-months
(H,L) Change web user interface in < 4 person weeks
Availability
H/W failure
(L,H) Power outage at Site 1 requires traffic re-direct to Site 2 in < 3 secs
(M,M) Restart after disk failure in < 5 mins
(H,M) Network failure is detected and recovered in < 1.5 mins
COTS S/W failures
Security
Data confidentiality
(L,H) Credit card transactions are secure 99.999% of time
Data integrity
(L,H) Customer database authorization works 99.999% of time

Scenario Utility Tree

- Utility
  - Performance
    - Data latency
      - Minimize storage latency on customer DB to 200 ms
      - Deliver video in real time
    - Transaction throughput
      - Maximize average throughput to authentication server
  - Modifiability
    - New Product Categories
    - Change COTS
      - change web user interface in < 4 person weeks
  - Availability
    - Hardware Failure
      - power output at site 1 requires traffic redirect to site 3 in < 3 s
      - network failure is detected and recovered in < 1,5 min
  - Security
    - Data confidentiality
      - customer database authorisation works 99,999% of time

Scenario Brain Storming

Sc#	Description	Quality Att.	Votes
4	Dynamically replan a dispatched mission within 10 minutes.	Performance	28
27	Split the management of a set of vehicles across multiple control sites.	Performance, Modifiability, Availability	26
10	Change vendor analysis tools after mission has commenced without restarting system.	Integrability	23
12	Retarget a collection of diverse vehicles to handle an emergency situation in less than 10 seconds after commands are issued.	Performance	13
14	Change the data distribution mechanism from CORBA to a new emerging standard with less than six person-months' effort.	Modifiability	12

Business Drivers

Phase - 1

Architec
t Centric

Concentrates on eliciting and analyzing architectural information.

Phase - 2

Stakeholder Centric

Elicits points of view from a more diverse group of stakeholders, and verifies the results of the first phase

Scenario:	E-connector looses connection with SAP
Attribute:	Availability
Stimulus:	Temporary network fault
Response:	The system has an overall availability of 99,25% (max 2 hour down/ month)

Architectural decision	Sensitivity	Trade-off	Risk	Non-risk
DCTM content server runs on a clustered environment with 2 nodes	Common mode failure can not be handled			Probability of common mode failure is low
Integration relationship between SAP and Documentum is 'data consistency‘ and is not protected	Human user must report malfunction		From complaint to resolution > 2 hours	

Scenario:	Invoice poster needs e-document for data entry in SAP/R3
Attribute:	Perfomance-Latency
Stimulus:	Document request to Documentum
Response:	Document is available for processing in less than 10 s

Architectural decision	Sensitivity	Trade-off	Risk	Non-risk
E-documents are scanned in color at 200 dpi	Size of document is sensitive to quality of scanning	Usability vs Performance	Document too large for roundtrip in 10 s.	
E-documents are not cached	Every document must be fetched from DMTM	Development cost vs bandwidth cost	Document roundtrip time exceeds 10 s.	

Gather Architectural Requirements

- Brainstorm for Constraints & Quality Scenarios

  # make Communication decisions
  # make CrossCutting decisions

Evaluate Architectural Decision

Used a Event Bus to loosely couple the system

Used a GraphDb to search trains efficiently

Used a Cache db for frequent search

Decomposed the system in Microservices

Microservices are deployed in K8s cluster

…

As a user I want to search for a train from Mobile Client . The search result is shown to user In < 3 secs	Used a GraphDb to search trains efficiently	Support for Graphdb ?
	Used a Cache db for frequent search	How to handle the expiry of cache
The database System Crashes In the Data Centre During Operational Hours Secondary is made Primary In < 2 minutes	Shard based on Zones (4)	
	Add 2 Secondary nodes for DB	
As a user I want to use the portal when 100000 users(peak load) are active	K8s Autoscale of pods	
	Microservice	
	Used a Cache db for frequent search
